

vsini0

Notes: Here we provide the single-star model of vsini0, with the following parameters:

$T_{\text{eff}} = 20000$ K, $\log g = 375$, $v \sin i = 60$ km/s, $v_{\text{rad}} = -10$ km/s

For a single star model of low $v \sin i = 0$, we could observe the two thin components of Mg II 4481.

But for this Mg II 4481 line, there is a broader component on the right hand side.

Hence, they might be from two different stars, rather than a single star.
